Agile Development

Agile development is one of many approaches to project management that is used in software development. This method allows the programmer to respond to unpredictable errors when creating software. The main objective of agile development is to work in sprints, a set period of time during which specific work is to be completed. The agile development methodology also allows for work to be reviewed more frequently than it would be if a programmer were using a different method of project management. The software development process has few differences to the agile development method as the former allows you to go back at any point during the work process and look back at your mistakes. As a programmer I feel as if the agile development method would work better because it allows me to work at a steady pace throughout and constantly be checking my work at the end of each milestone.
